AL-FARABI KAZAKH NATIONAL UNIVERSITY

FACULTY OF INFORMATION TECHNOLOGY AND ARTIFICIAL INTELLIGENCE
DEPARTMENT OF CYBERSECURITY AND CRYPTOLOGY

LEGAL REGULATION OF INFORMATION SECURITY

Lecturer: PhD, Acting Associate Professor Assem Turarbek

MODULE 2

PUBLIC INSTITUTIONS AND E-GOVERNMENT

LECTURE 9

UNIFIED TRANSPORT NETWORK OF STATE BODIES

LECTURE OBJECTIVE

Explain how the Unified Transport Network supports interagency exchange and how external Internet and e-mail gateways serve different traffic flows.

LECTURE PLAN

1. Purpose and scope of the Unified Transport Network

2. External Internet and e-mail gateways

3. Security and service continuity

PURPOSE AND SCOPE

Concept or participant	Meaning, duties and application
Unified Transport Network	An e-government telecommunications environment for exchange between connected public-sector networks.
Connected organizations	The lecture covers state bodies, subordinate organizations, local government and other designated entities.
Policy objective	Shared requirements support consistent security and reduce duplicated network operation costs.

The shared transport environment supports electronic government by connecting participating networks under common requirements. This arrangement aims to rationalize operating costs and security measures. Its scope is determined by the participating entities and permitted network connections. External access introduces additional controls at the boundary of that environment.

INTERNAL NETWORK EXCHANGE

Concept or participant	Meaning, duties and application
Local networks	Participating local networks exchange data through the common transport environment. The lecture distinguishes local networks with direct Internet access.
Departmental networks	Connect services used by agencies and subordinate organizations.
Corporate networks	Support exchange between the participating organizations and shared infrastructure.

A transaction between agencies relies on each application, the local networks and the shared communication service. Working connectivity alone does not establish that the receiving application accepted the data. Operational diagnosis therefore compares network status with application records and the outcome of the exchange.

CONNECTIONS BEYOND THE TRANSPORT NETWORK

Concept or participant	Meaning, duties and application
Public telecommunications	Connections between participating networks and public or other telecommunications networks follow the uniform ICT and security requirements.
Internet access	The lecture describes telecom operators routing Internet traffic for covered entities through a unified Internet access gateway.
Contractual arrangements	Operators connect to the gateway and carry traffic under contractual terms.

Connections with public networks follow the uniform ICT and security requirements described in the source. Telecom operators carry covered Internet traffic through the unified access gateway on contractual terms. Specific operational exceptions apply to designated institutions. The existence of an exception is assessed under its own conditions.

EXTERNAL E-MAIL

E-government e-mail gateway

Routes correspondence between state-body mail systems and external e-mail services.

Separation of functions

The transport network carries internal exchange. The Internet access and e-mail gateways handle their respective external flows.

Operational exceptions

The lecture describes specific exceptions for designated public institutions under applicable procedures.

External correspondence passes through the e-government e-mail gateway in the arrangement described. Delivery records show whether a message left the sender, reached the gateway and passed to the external service. These records help distinguish a local mail problem from a gateway or external delivery problem.

OPERATIONAL SECURITY AND RELIABILITY

Segmentation

Separating internal networks and external services helps limit the effects of a disruption.

Monitoring

Availability and security monitoring identify failures affecting interagency traffic.

Continuity

Responsibilities and recovery arrangements define how operators and participating agencies restore exchange.

Monitoring identifies failures and helps estimate their scope. A common outage across several agencies suggests a shared dependency, while one affected agency may indicate a local fault. Restoration checks include both network exchange and the application result. Change records help connect a new fault to a recent configuration action.

CASE DISCUSSION

Two agencies can exchange records, but neither can send messages to an external e-mail address.

Which part of the infrastructure should the teams check first, and what does the working exchange tell them?

Analysis

Start with the external e-mail gateway and mail delivery records. Working interagency exchange suggests that the shared internal network still carries that traffic. Monitoring and continuity planning help identify and isolate faults.

NETWORK BOUNDARIES AND PERMITTED EXCHANGE

The Unified Transport Network links designated local, departmental and corporate networks. The lecture excludes local networks with Internet access from the internal exchange arrangement it describes.

Connections with public telecommunications networks follow additional requirements. The boundary between internal exchange and external connectivity is therefore an important part of the architecture.

The Internet gateway serves the external traffic of covered networks through participating telecommunications operators. Contractual arrangements define connection and traffic handling.

The e-mail gateway handles exchange between state-body mail and external mail. Mail failure and general Internet failure may have different causes and require different operational checks.

A SERVICE DISRUPTION ACROSS AGENCIES

A registry exchange depends on the originating application, its local network, the transport environment and the receiving service. A failure in any of these components can interrupt the transaction.

A diagnosis compares application errors with network status and the experience of other connected agencies. The pattern of failures helps identify whether the problem is local or shared.

Participating organizations and operators need clear responsibility for connection, monitoring and fault resolution. Change records help identify whether a recent configuration change affected the service.

Recovery also includes confirming that the expected agencies can exchange data again. Monitoring after restoration helps detect recurring faults or unintended access paths.

CONCLUSION

1. The Unified Transport Network supports exchange between participating public-sector networks.

2. External Internet and e-mail traffic use separate gateway functions in the arrangement described.

3. Monitoring and continuity planning help identify and isolate faults.

SELF-ASSESSMENT QUESTIONS

1. What is the main purpose of the Unified Transport Network?
2. How does internal interagency exchange differ from external Internet access?
3. What functions do Internet and electronic mail gateways perform?
4. Which records would help investigate an email delivery failure?
5. Why does network connectivity alone not prove that an electronic service is functioning correctly?
